

Protecting Data in Transit

Ben Piper

AWS CERTIFIED SOLUTIONS ARCHITECT

<https://benpiper.com>

Transport Layer Security (TLS)

People sometimes incorrectly call this SSL
(secure sockets layer)

HTTPS uses TLS

Encrypting Data in Transit

Configure application to use TLS

Application-dependent configuration

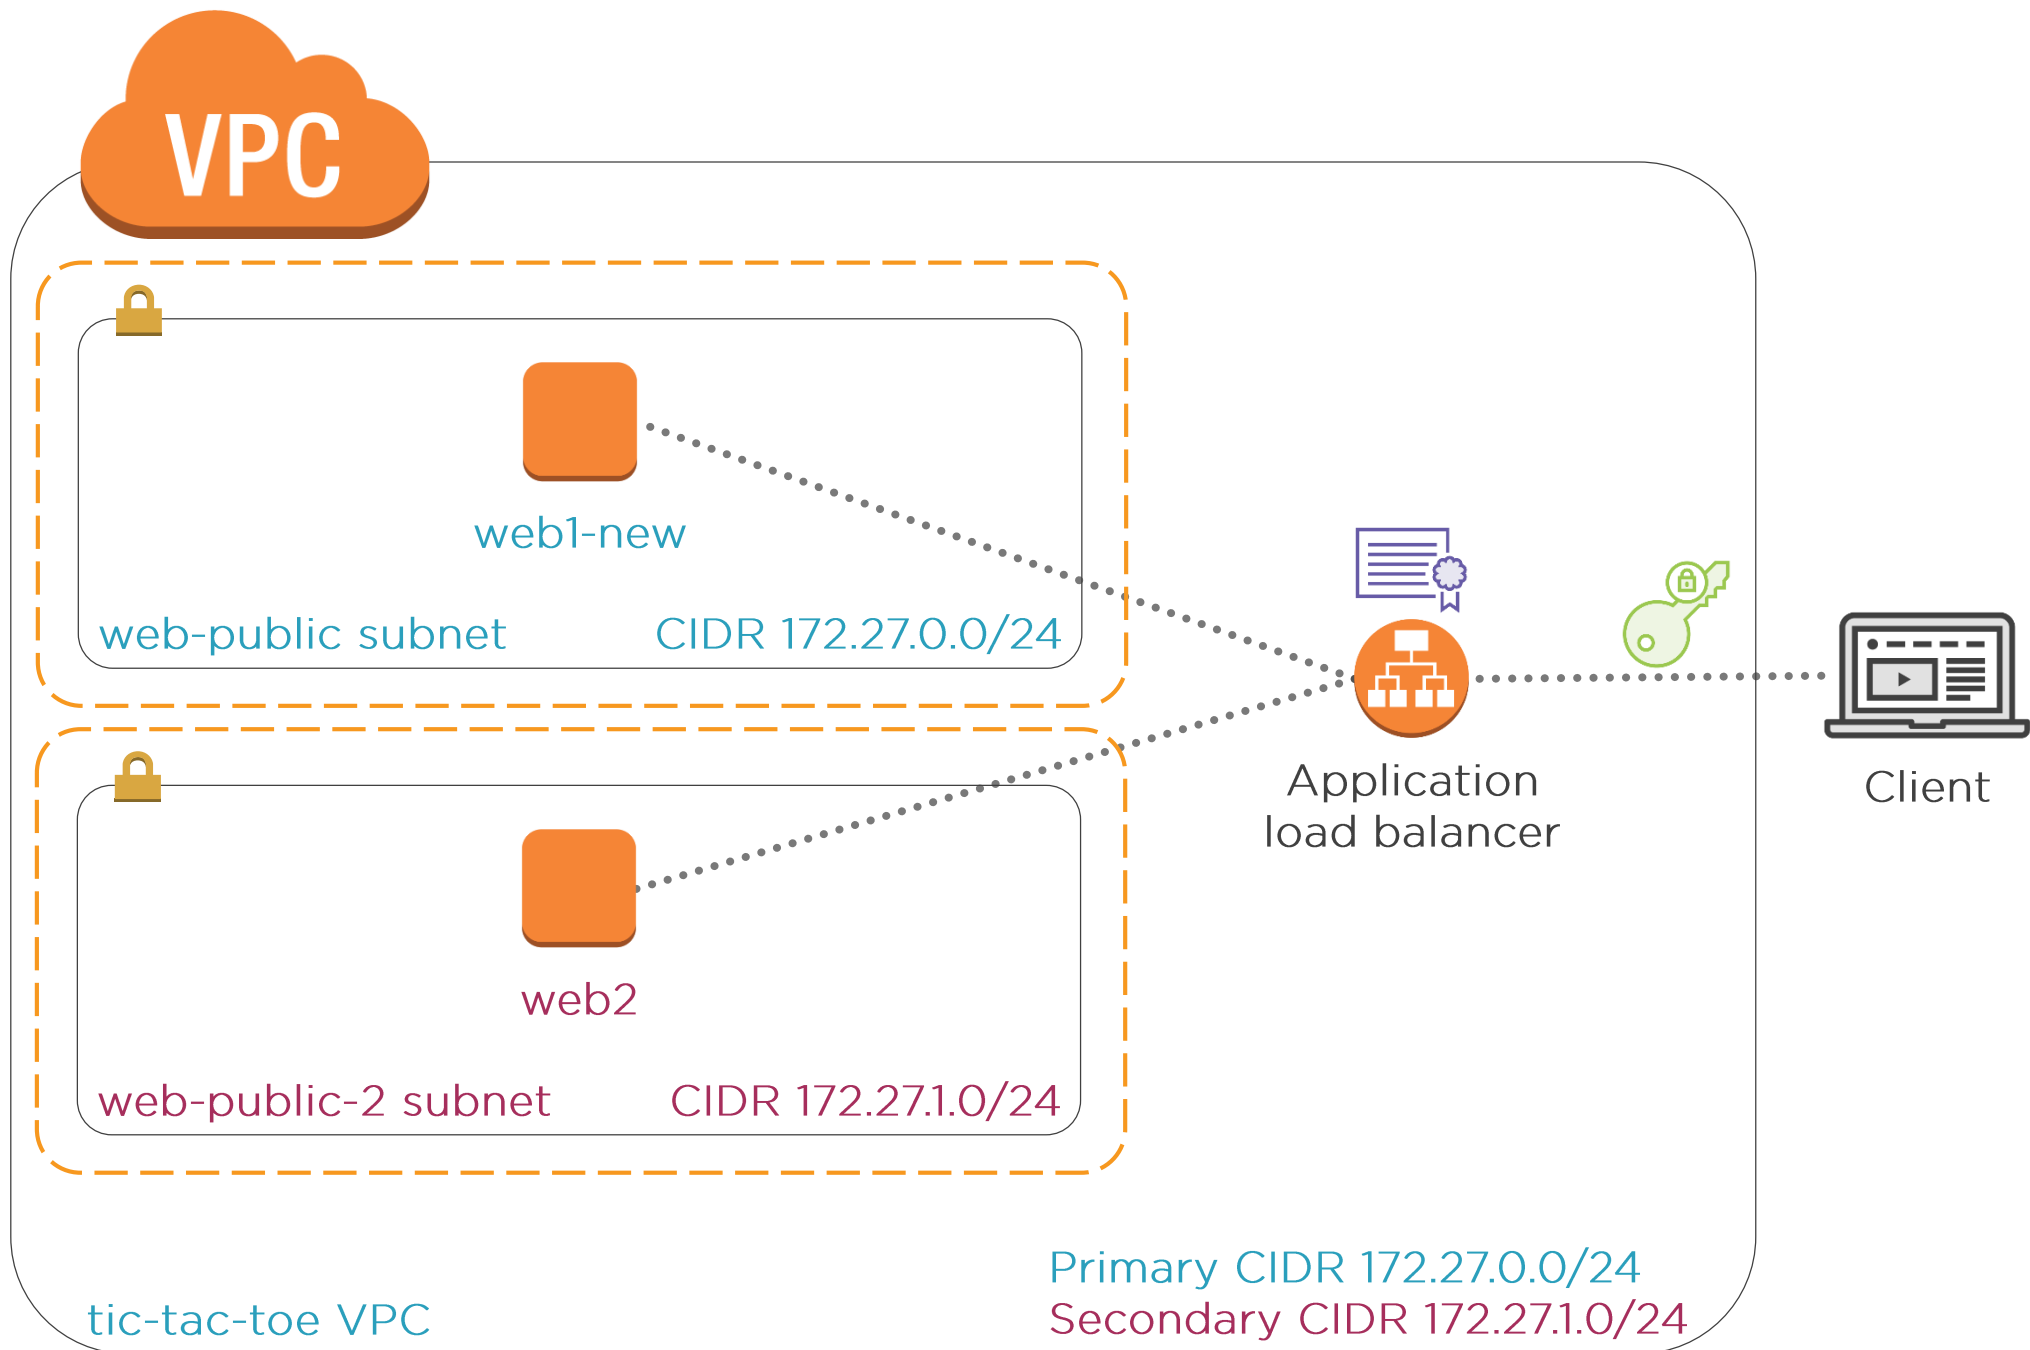

Independent of AWS

Application Load Balancer

Configure AWS Application Load Balancer to use TLS

Force all clients through the load balancer

AWS Networking Deep Dive: Elastic Load Balancing (ELB)

- Securing Web Applications with HTTPS*

Module Overview

Prepare the infrastructure to support an Application Load Balancer

Create a secure Application Load Balancer

Demo

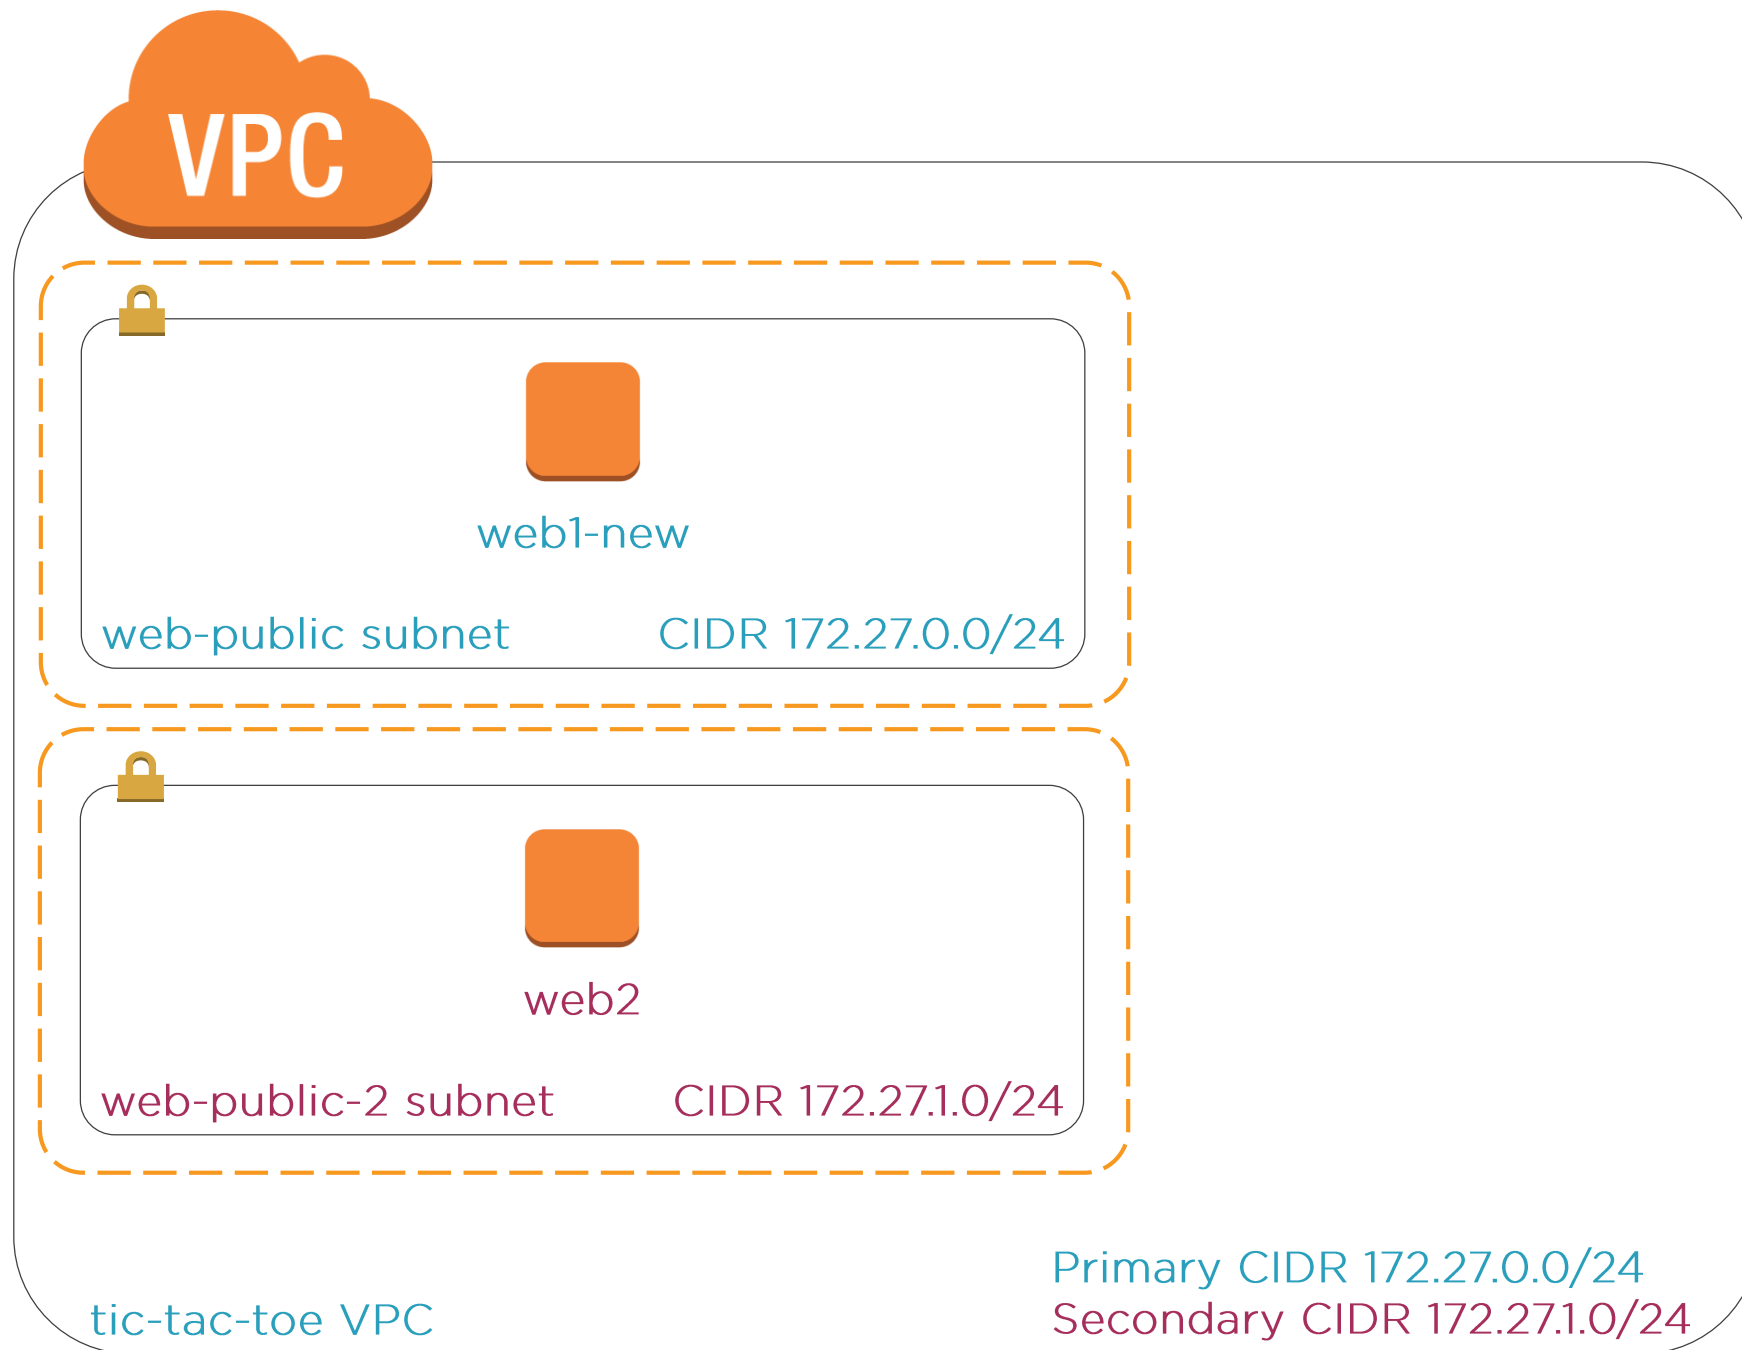

Create a new subnet in a different zone

Bring up an instance named web2

Launch the application

Reconfigure security group

Demo

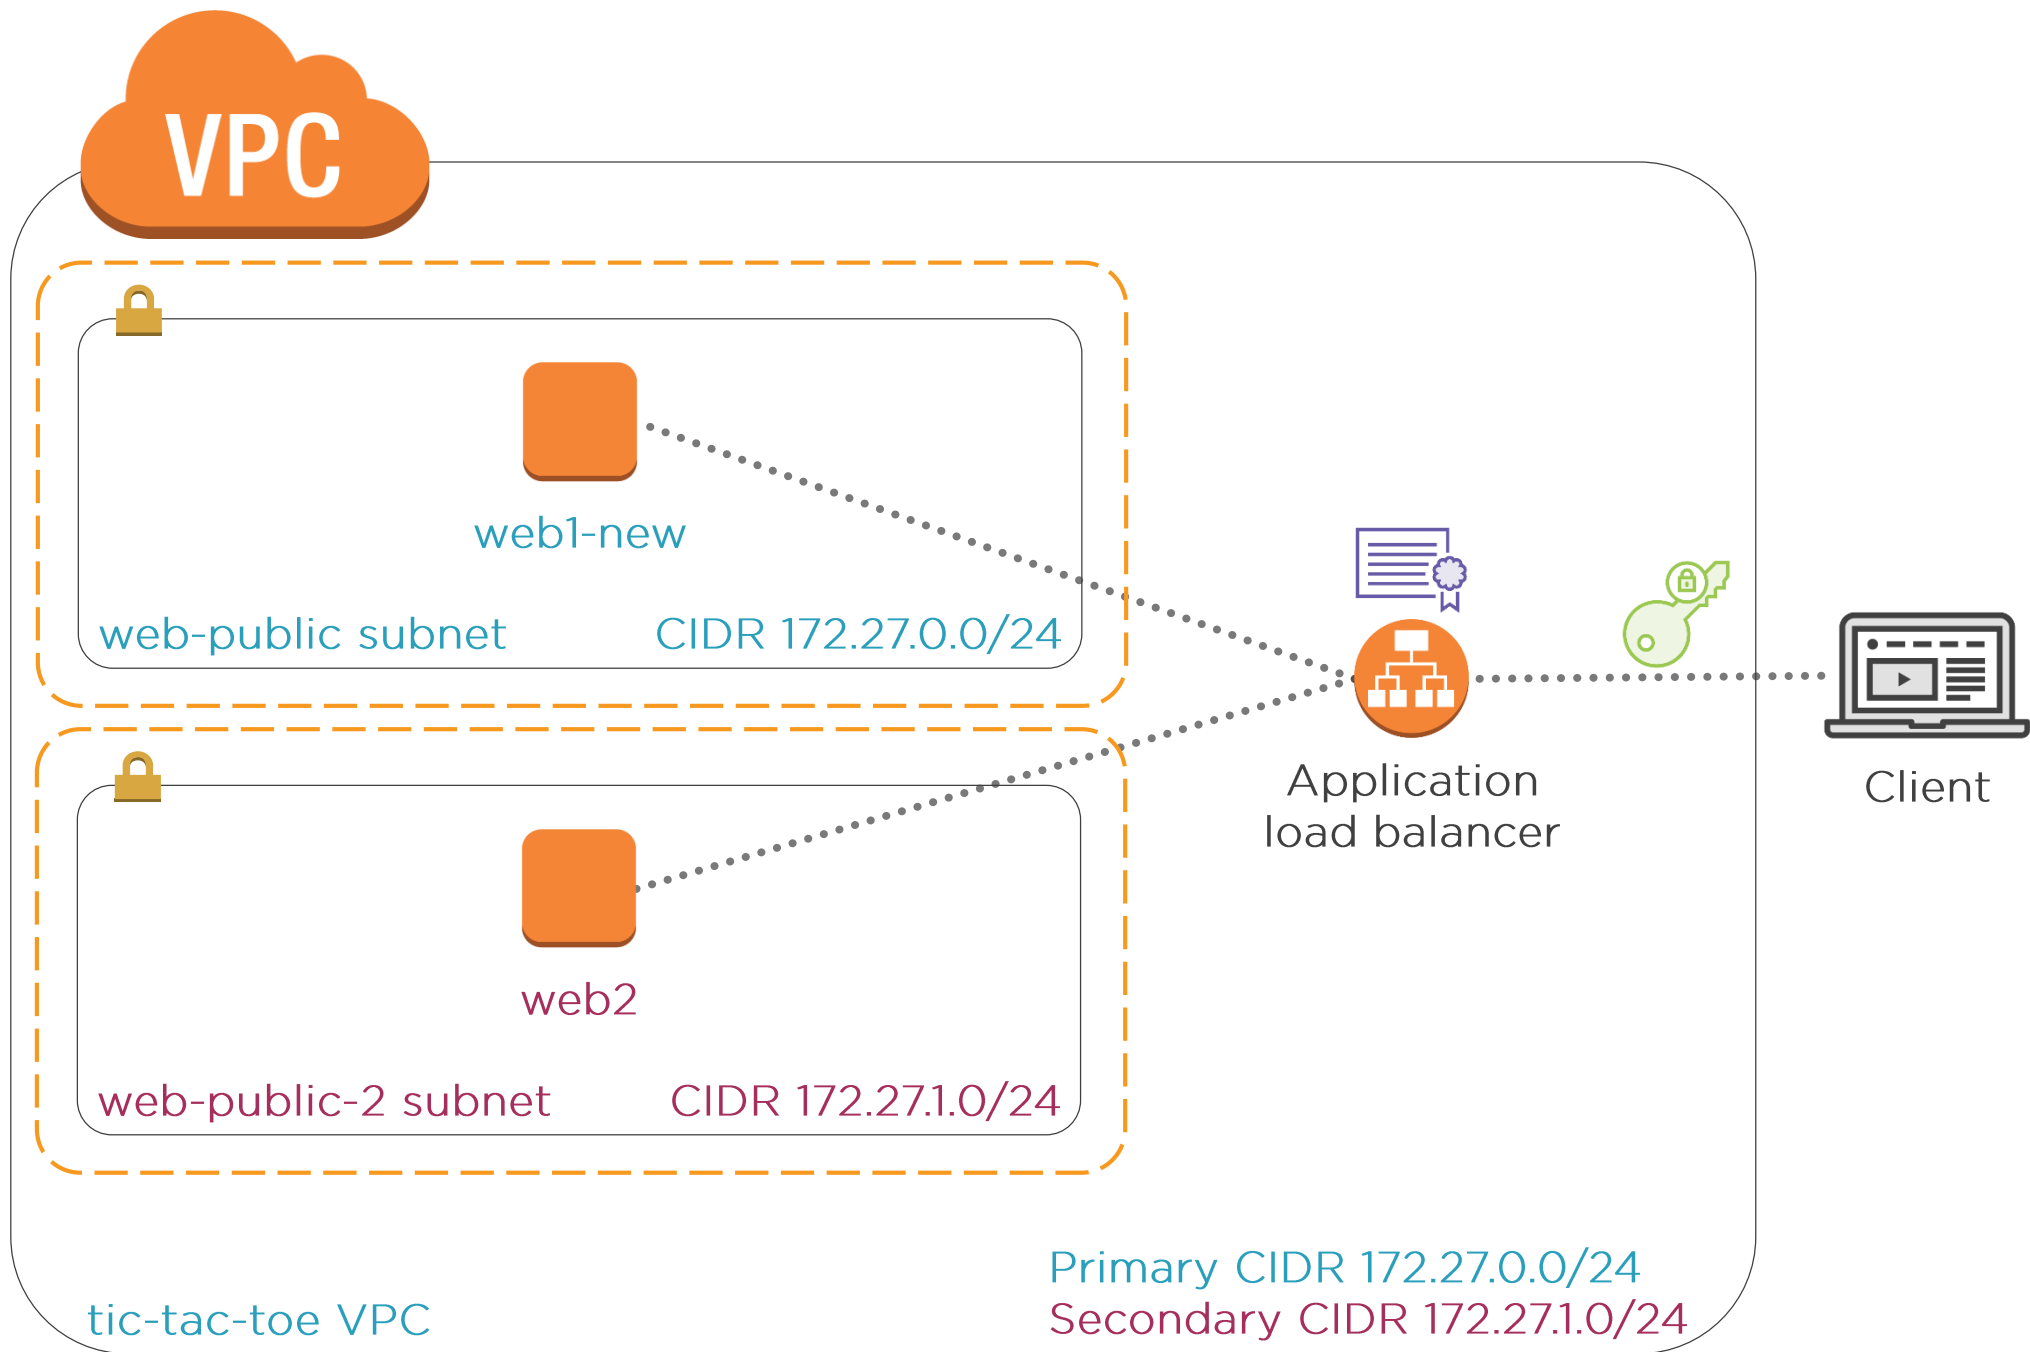

Use the AWS Certificate Manager to create a TLS certificate

Create an Application Load Balancer

Create a DNS record for the application

Browse to the application using HTTPS

Summary

Choose where to terminate the TLS connection

- Individual instances
- Application Load Balancer

ALB requires two availability zones

ACM requires you to verify control of the domain name in the certificate

For private network connectivity, see *AWS Networking Deep Dive: Virtual Private Cloud (VPC)*
